(54) Deformable intraocular lens structures and methods and devices for implantation

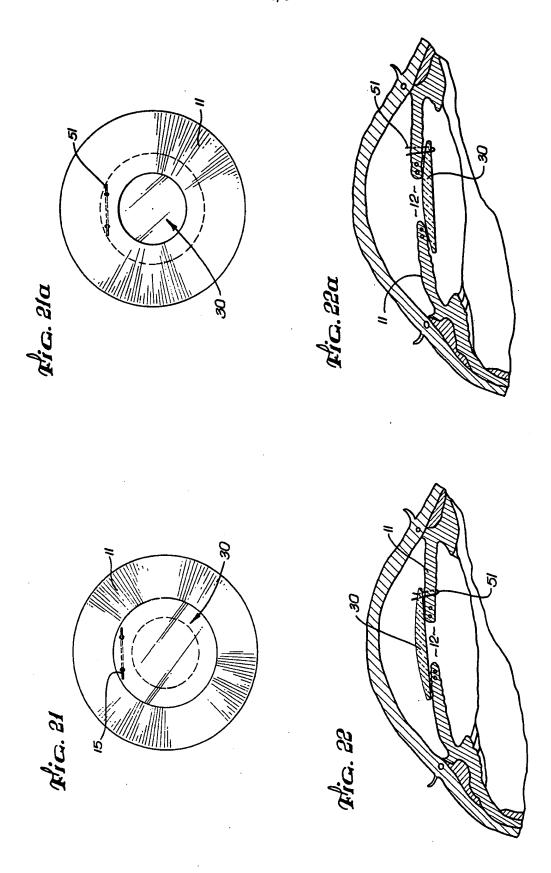

(57) An intraocular lens which is used as an artificial lens implant in an eye has a deformable optical zone with known memory characteristics. These enable the lens to be deformed, such as by compressing or rolling, to 80% or less of the cross-sectional diameter of the optical zone in an unstressed state, but allow the lens to return to its original configuration and fixed focal length after implantation.

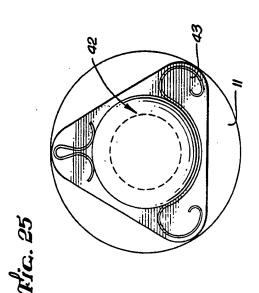

Various surgical devices are disclosed for deforming the lens, which device may have a shaft having at one end a member engageable with a distal portion of the lens and another member engageable with a proximal portion of the lens. The two members are movable one

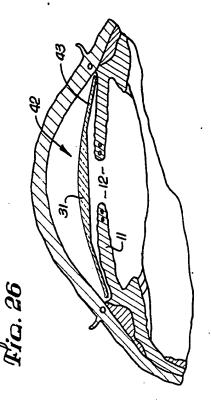

relative to the other to effect deformation of the optical zone of the lens during insertion of the lens into the eye. Micro-hook and injection type devices are also shown.

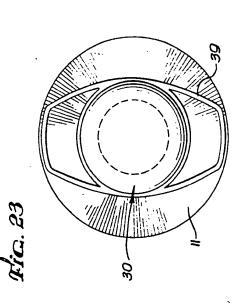

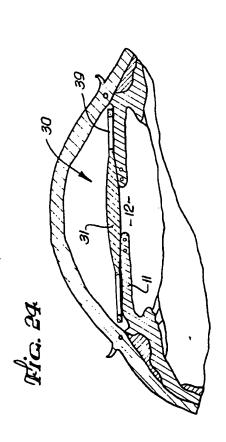

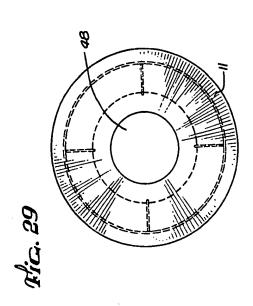

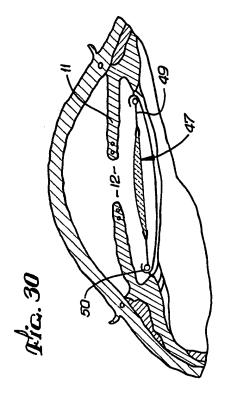

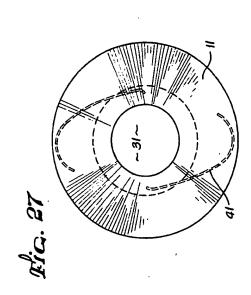

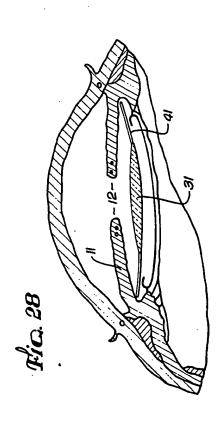

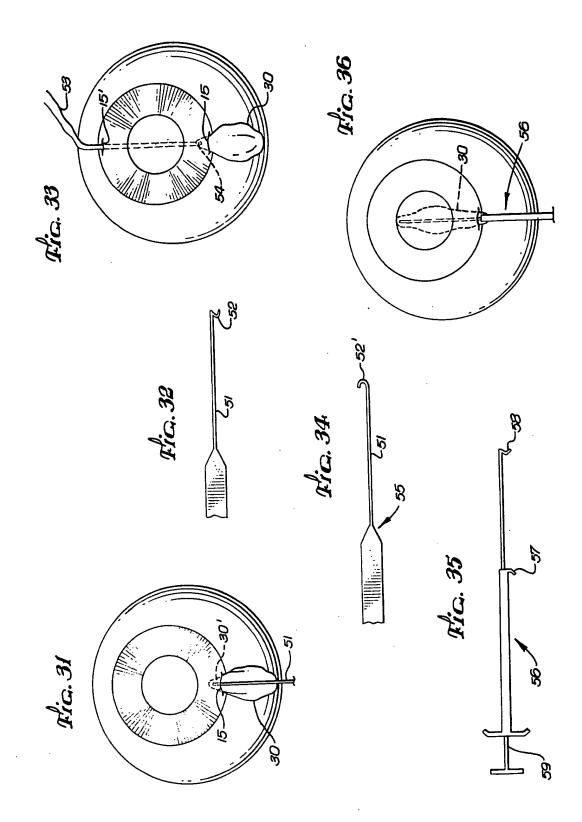

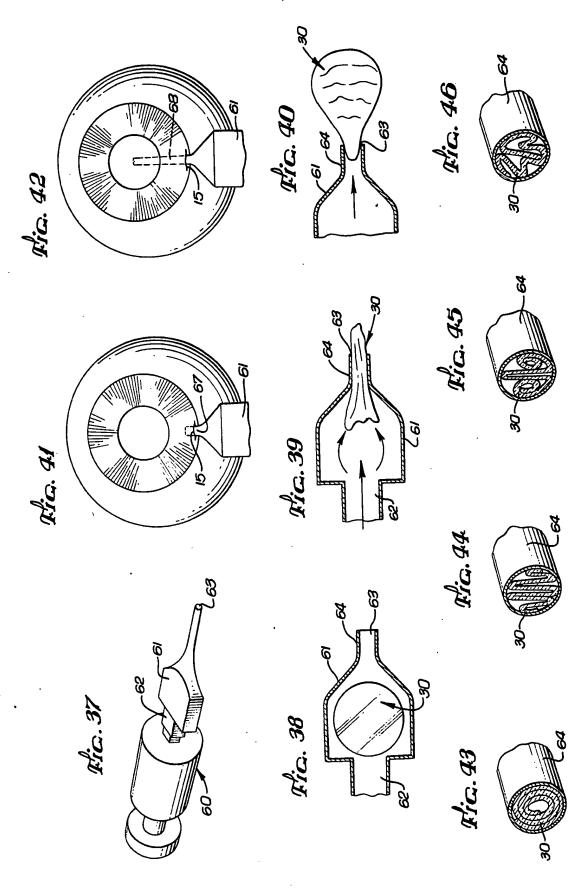

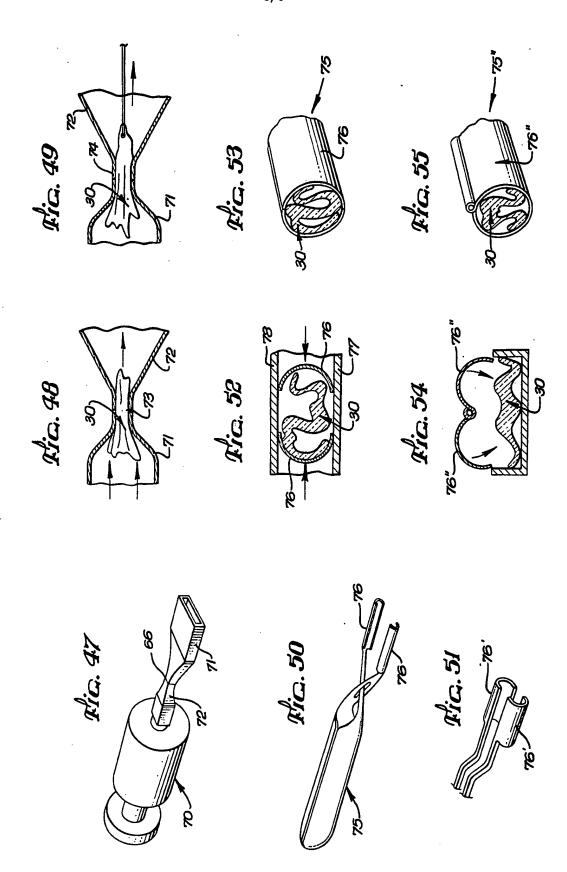

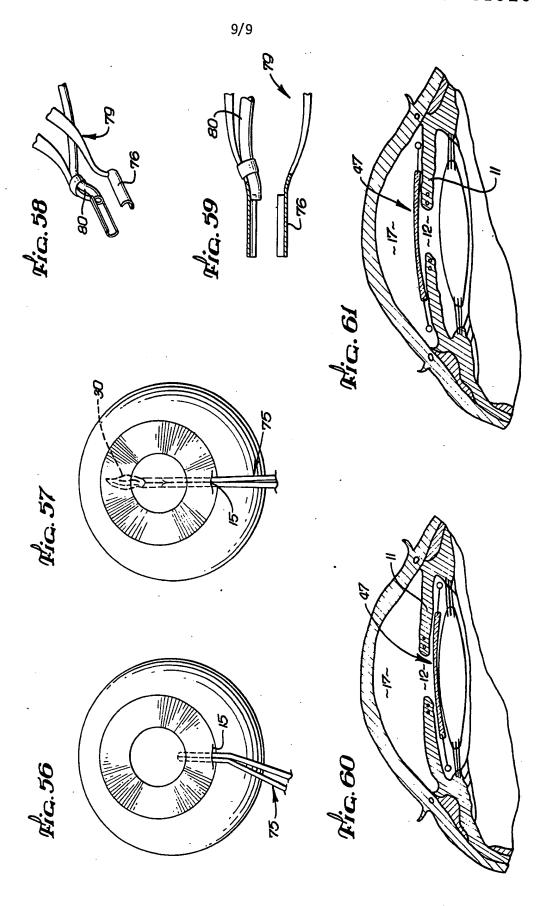

GB 2 114 315A

5

SPECIFICATION

Deformable intraocular lens structures and methods and devices for implantation

Background of the Invention Intraocular lenses have gained wide acceptance in replacement of human crystalline lens after a variety of cataract removal procedures.

10 The human crystalline lens is generally recognized to be a transparent structure having a thickness of about 5 millimeters and diameter of about 9 millimeters. The lens is suspended behind the iris by zonular fibers which con-

15 nect the lens to the ciliary body. A lens capsule surrounds the lens, the front portion of the capsule being commonly known as the anterior capsule and the back portion commonly known as the posterior capsule.

20 Numerous procedures for the removal of cataracts have been developed in which the lens is removed from the eye and replaced by an artificial lens implant. The extraction procedure may be generally categorized as intracap-

25 sular (in which the lens is removed together with the lens capsule) or extracapsular (in which the anterior capsule is removed with the lens, and the posterior capsule is left intact).

30 Since Ridley implanted the first artificial lens in about 1949, the problems associated with cataract extraction and lens implantation have received a great deal of attention from ophthalmic surgeons.

35 Various types of artificial lenses have been proposed, and appropriate surgical procedures have been developed which strive to reduce patient discomfort and reduce post-operative complications. Reference is made in this connection to *Pseudophakos* by N. Jaffe, et al;

"History of Intraocular Implants" by D.P. Choyce (Annals of Ophthalmology, October 1973); U.S. Patent No. 3,991,426 issued to Flom on November 16, 1976; and U.S. Pa-

45 tent No. 4,092,743 issued to Kelman on November 8, 1977 which disclosures are hereby incorporated by this reference.

Of particular interest in the context of the present invention is the development of surgi50 cal techniques requiring relatively small incisions in the ocular tissue for the removal of cataracts as disclosed in U.S. Patent No.
4,002,169 and U.S. Patent No. 3,996,935.
A number of skilled artisans have disclosed
55 intraocular lens structures comprising an opti-

5 intraocular lens structures comprising an optical zone portion generally made of rigid materials such as glass or plastics suitable for optical use.

However, one of the principle disadvan-60 tages of the conventional rigid intraocular lens is that implantation of the lens requires a relatively large incision in the ocular tissue. This type of surgical procedure leads to a relatively high complication rate, among other gers associated with implantation of a rigid lens structure include increased risks of infection, retinal detachment, and laceration of the ocular tissues, particularly with respect to the 70 pupil.

Accordingly, those skilled in the art have recognized a significant need for an intraocular lens implant which affords the clinical advantages of using relatively small incision

75 techniques, yet possesses an optical zone portion having a fixed focal length and which will retain a prescribed configuration once, implanted in the central optical area, thereby providing a safer and more convenient surgi-

80 cal procedure and confortable fit for the eye. The present invention fulfills these needs.

SUMMARY OF THE INVENTION

This invention relates to improved intraocu-85 lar lens structures, methods and instrumentation for implantation of the lens through a relatively small incision made in the ocular tissue. In more detail, the inventive lens structures comprise a deformable optical zone por-

90 tion having prescribed memory characteristics which enable the lens to be deformed by compressing, rolling, folding, stretching, or by a combination thereof, to a diameter of 80% or less of the cross-sectional diameter of the

95 optic, and yet return to its original configuration, full size and fixed focal length after insertion in the eye. The unique optical zone portion can be fabricated from selected biologically inert materials possessing superior

100 elasticity and compression characteristics and optionally, may include a wide variety of support appendages.

The embodied methods for implantation of the artificial intraocular lens can be utilized for 105 replacement of, or for refractive correction of, a human crystalline lens. These inventive methods include:

providing an intraocular lens having a deformable optical zone portion with pre-110 scribed memory characteristics; deforming the optical zone portion of the lens to a diameter of about 80% or less of the crosssectional diameter of the optic in an unstressed state; inserting the intraocular lens 115 through a relatively small incision made in the ocular tissue; allowing the lens implant to return to its original configuration, full size and fixed focal length after insertion in the eye; whereby a safer, more convenient surgical procedure and more comfortable fit 120 for the eye is achieved.

Further, the present invention provides unique instrumentation for deforming and inserting the lens through a small incision during

125 implantation. In one embodied form, the instrumentation comprises a single micro-hook type device adapted to fit the lens to enable the lens to be appropriately deformed and pulled through the incision made in the ocular

25

micro-hook type device is provided which enables the lens to be stretched in a direction perpendicular to the incision in an amount sufficient to allow insertion of the lens through a relatively small incision made in the ocular tissue. In yet a third embodied form,

the instrumentation comprises an injection type device especially adapted to compress the inventive lens through a cannula and insert the lens into the eye. In a fourth

embodiment, the instrumentation comprises a forceps type device having a compressor member to partially or fully encase and deform the intraocular lens to facilitate insertion within the eye.

Thus, the present invention offers a unique implantation system for correction of or replacement of a human crystalline lens after, for instance, cataract removal by way of small 20 incision technique.

The above and other objects and advantages will become apparent from the following more detailed description of the invention, taken in conjunction with the drawings.

chamber of the eye for corrective purposes. DESCRIPTION OF THE PREFERRED EMBODI-

MENTS

The present invention provides deformable intraocular lens structures having prescribed memory characteristics and methods and instrumentation for implantation of such lens for correction of or replacement of a human crystalline 10 lens. A unique optical zone portion of the intraocular lens possesses memory characteristics such that the lens can be deformed by compressing, rolling, folding or stretching the optical zone portion to a diameter of 80% or less than the cross-sectional diameter of the optic during insertion into the

eye, thereby providing a safer, more conve-65 nient, and more comfortable surgical proce-

eye yet return to its original configuration, size

and fixed focal length once implanted in the

dure.

Referring now to the drawing, denoted Fig. 1, there is shown a stylized frontal view of an eye illustrating the major ocular components:

- 70 iris 11, pupil 12, limbus 13, sclera 14 relative to a small incision 15 made in the ocular tissue, for instance, implantation of an intraocular lens in accordance with the present invention.
- 75 Fig. 2 represents a side cross-sectional view of the eye shown in Fig. 1 and illustrates major ocular components in more detail. The cornea 16 is composed of clear tissue which connects to the sclera 14 at the limbus 13.
- 80 The anterior segment of the eye is divided into two principle chambers by the iris 11 and pupil 12. An anterior chamber 17 is defined by the space between the cornea 16 and the iris 11. A posterior chamber 18 is defined by 85 the space between the iris 11 and the vitreous 19.

In surgical procedures commonly known as intracapsular cataract extraction, the posterior chamber 18 is bounded by the hyloid mem-

- 90 brane 20. In surgical procedures commonly known as the extracapsular cataract extraction, the posterior chamber 18 is bounded by the posterior capsule 21 attached to the ciliary body 22 by means of zonular fibers 23.
- 95 Portions of the anterior capsule may remain as flaps 24, creating, with the posterior capsule, 21 the ocular portion commonly known as the "capsular bag". The posterior chamber 18 peripheral area between the iris 11 and the
- 100 extension of the ciliary body 22 is referred to as the ciliary sulcus 26. The anterior chamber peripheral area between the cornea 16 and the iris 11 is referred to as the angle 27 of the eye. The area of the sclera posterior to the
- 105 plane of the iris and anterior to the vitreous 19 is known as pars plana 28.

With the foregoing referenced ocular components in mind, it is a principle feature of the present invention to provide a class of intrao-

- 110 cular lens structures having a deformable optical zone portion such that the lens with optional fixation appendages can be deformed by compressing, rolling, folding or stretching to a diameter of 80% or less of the cross-
- 115 sectional diameter of the optic during insertion into the eye, yet return to its original full size and fixed focal length once implanted in the eye. Accordingly, the inventive intraocular lens structures can be implanted through
- 120 smaller incisions made in the ocular tissue than would be possible with any rigid intraocular lens of comparable size.

Fig. 3 depicts an intraocular lens 30 in accordance with the present invention which

125 is suitable for use as an artificial lens implant. In the embodied form shown, there are no fixation appendages and the lens comprises a deformable optical zone portion 31 imparted with desirable memory characteristics, appro-

130 priate structural dimensions, and composed of

a deformable material such that the lens can be deformed to an appropriate size for insertion into the eye.

Typically, the optical zone portion 31 of the lens 30 is composed of one or more suitable materials such as polyurethane elastomer, silicone elastomer, hydrogel polymer collagen compounds, organic or synthetic gel compounds and combinations thereof. In one em10 bodied form, the optical zone portion 31 of the lens can be fabricated having a base member composed of any of the foregoing materials, and further comprise a surface layer or layers of a second or third material. More15 over, the lens may be tinted, colored or fabricated with occluded portions to yield desired transmission effects.

As shown in Figs. 4, 5, 6, 7, and 8, the inventive lens can be fabricated having a wide 20 variety of cross-sections designed for replacement of the surgically removed human crystalline lens or for refractive correction without removal of the human crystalline lens. In this respect, the Figs. 4–8 illustrate respectively a 25 convex lens 32, a plano convex lens 33, a plano concave lens 34, a biconcave lens 35, and a concave-convex lens 36.

Referring to Fig. 9, there is illustrated another embodied intraocular lens structure 30 37 in accordance with the present invention, the lens being provided with means 38 for assisting suturing, manipulation, or fluid flow through the lens. In this respect, the lens may optionally be provided with one or more holes 38, suitably located, which may extend entirely through the cross-section of the lens as shown in Fig. 10, or partially through the cross-section of the lens as an indentation for facilitating maneuvering of the lens during 40 surgical procedures.

Further, in accordance with the present invention, the inventive intraocular lens structures may comprise integral or nonintegral appendages to facilitate positioning of the lens 45 within the eye. Figs. 11–20 illustrate a wide variety of appendages which may be utilized.

In more detail, Fig. 11 depicts an intraocular lens 30 optionally provided with appendages 39 of the compressible-integral support 50 element type. As seen in Fig. 12, the appendages 39 in this embodiment are uniplanar with the optical zone portion 31 of the lens.

Figs. 13 and 14 depict the inventive intraocular lens provided with a plurality of holes 55 40 therethrough and angulated support appendages 41 with respect to the plane of the optic. Such appendages may be composed of any suitable material and may be selected from a material different from that of the 60 optical zone portion of the lens.

Figs. 15 and 16 illustrate an inventive intraocular lens 42 provided with angulated compressible appendages 43 with internal supporting elements. That is, the supporting

appendages as shown.

Figs. 17 and 18 depict an inventive intraocular lens 44 having a deformable peripheral support ring 45 and a tinted or occluded 70 periphery 46 which is a substantially continu-

ous peripheral flange.

Figs. 19 and 20 illustrate yet another intraocular lens structure 47 in accordance with the present invention wherein the optical zone 75 portion 48 is suspended by threads or spokes 49 from a peripheral supporting ring 50 constructed of a suitable material.

As will readily be appreciated by those skilled in the art, the foregoing specific em-80 bodiments are merely illustrative of the wide variety of intraocular lens structures included within the spirit and scope of this invention. In this respect, it should be understood that the provision of appendages and means for

85 facilitating manipulation, fixation or fluid flow through the lens are optional. The latter means includes holes, openings, depressions and/or passageways to aid the surgical procedure.

90 Figs. 21 and 22 illustrate implantation of the intraocular lens 30 fixated to the iris 11 of the eye in front of the pupil 12. In the depicted embodiment, a piercing suture 51, such as one fabricated from stainless steel, is

95 disposed at an appropriate location along the lens periphery and inserted through the iris 11 in a surgical procedure which replaces the human crystalline lens previously extracted from the eye. While the foregoing figures

100 illustrate fixation of the lens 30 shown in Fig. 3, it should be readily understood that each of the foregoing embodied lens structures could be also fixated in a similar manner.

Figs. 21a and 22a illustrate an alternative 105 positioning of the intraocular lens 30 in accordance with the present invention, behind the iris 11 of the eye, behind the pupil 12. In the illustrated embodiment, the lens 30 is also sutured in place by means of a piercing suture 110 51 such as one composed of stainless steel.

Figs. 23 and 24 depict a typical positioning of the intraocular lens 30 shown in Figs. 11 and 12 in the anterior chamber of the eye in front of the iris 11, with supporting appen-

115 dages 39, to fixate the optic over the pupil 12. In these illustrations the lens is shown without the optional internal supporting elements

Figs. 25 and 26 illustrate positioning of the 120 intraocular lens 42 shown in Figs. 15 and 16 in a position in front of the iris 11 and the pupil 12 with supporting appendages 43 angulated with respect to the plane of the optic.

Figs. 27 and 28 illustrate placement of the 125 intraocular lens shown in Figs. 13 and 14 in a position behind the iris 11 and pupil 12. The supporting appendages 41 are positioned in front of the ciliary body 22 and the optical zone portion of the lens is positioned in front

120 of the northeine concule 21

5

Figs 29 and 30 depict the intraocular lens 47 shown in Figs. 19 and 20 after implantation, and positioned behind the iris 11 and the pupil 12 within the capsular bag.

Accordingly, those skilled in the art will readily appreciate that the deformable intraocular lens implant provided by the present invention can be fixated in the eye in a wide variety of locations and that a wide variety of 10 supporting appendages may optionally be included with the deformable optical zone portion of the lens to fixate the lens in the desired position.

One important feature of the lens in accor-15 dance with the present invention is that it lends itself to positions which allow the free mobility of the pupil, that is, in terms of normal pupillary functions when in place in the eve.

20 The present invention further provides unique methods and devices for implantation of the intraocular lens by temporarily deforming the optical zone portion to a diameter of 80% or less of the cross-sectional diameter of the 25 optical zone portion in an unstressed state. After insertion into the eye, the optical zone portion returns to its prescribed original optical configuration, full size, and fixed focal length, thereby providing a safer, more conve-30 nient surgical proceduring and more comfortable fit for the eye.

Referring now to Figs. 31 and 32, there is illustrated a first embodied method comprising deforming the unique intraocular lens 30 by 35 pushing a distal porion 30', of the lens 30 through a relatively small incision 15 made in the ocular tissue. A specially designed implantation instrument which may generally be described as a single microhook device compris-40 ing a very thin, relatively rigid shaft 51 having an engagement bend 52 in the forward portion thereof to engage the distal rim or hole of the intraocular lens 30 may be utilized to effect insertion of the lens through the inci-45 sion 15. In this respect, the engagement bend 52 may be configured in a variety of ways, for instance, straight or outwardly curved bend, to facilitate engagement of the distal rim or hole in the intraocular lens 30.

Accordingly, the microhook device engaged 50 with the lens 30 is initially inserted through the incision 15 and the lens 30 undergoes deformation to an appropriate diameter by compression of the lens caused by the pres-55 sure exerted by the surrounding tissue around the incision 15. The lens 30 is thereafter fully inserted into the eye in a desired position. Optionally, the microhook implantation instrument can be provided with an additional tine 60 to prevent the rim of the lens from sliding over the needle, deleteriously releasing tension on the lens.

A second embodied method is depicted in Fig. 33, the method also features the use of 65 the surgical incision 15 to deform the intraocular lens 30. In this embodied form, the lens 30 is pulled through the surgical incision 15 by use of a connecting material 53, such as suture thread or the like. The connecting

70 material 53 has been inserted through a second microincision 15', on the opposite portion of the eye, and passed through a hole 54 provided in the periphery of the lens 30 and returned through the original incision 15. Ac-

75 cordingly, the two ends of the connecting material 53 are grasped and withdrawn which allows the lens 30 to be pulled into proper position into the eye. Once positioned inside the eye, one end of the connecting material

80 53 is released and the entire connecting material 53 is withdrawn, leaving the lens 30 in position. As shown in Fig. 34, a microhook type device 55 can be used in place of the connecting material 53 to pull the lens 30

85 into the eye from a second micro incision 15, made therein.

Referring now to Figs. 35 and 36, there is illustrated yet another embodied method for implantation of the lens 30 in the eye. In this 90 embodied form, a double microhook type device 56 shown in Fig. 35 is utilized to stretch the intraocular lens 30 in a direction perpendicular to the incision 15, thereby deforming the lens 30 in the plane of the incision 15

95 sufficiently to allow insertion of the lens 30 through a relatively small incision 15, without ocular tissue stress as featured in the foregoing embodiments.

The double microhook device 56, as shown 100 in Fig. 35, comprises parallel positioning of two needles 57 and 58, either co-axial or side-by-side, which facilitates one-handed operation by the surgeon. It should be understood however, that the same deformation can

105 be accomplished in a bimanual operation with, for instance, the two microhook devices 50 and 55, shown in Figs. 32 and 34.

In more detail, the device 56 depicted in Fig. 35 comprises a first needle 57 slideably 110 mounted in association with a second needle 58 in such a manner as to be used as a means for retaining the lens 30 by engaging the proximal portion of the lens 30 to stabilize the lens 30 while the second needle 58

115 engages a distal portion of the lens 30. The force necessary to deform the lens 30 is applied by means of the plunger 59b so as to move the two hooks 57 and 58 away from each other, thereby stretching the engaged 120 lens 30.

Referring now to Figs. 37 through 46, there is illustrated yet another embodied method and inventive device 60 for implantation of the deformable intraocular lens 30 in 125 accordance with the present invention.

More particularly, Fig. 37 depicts an implantation device 60 utilizing mechanical/hydraulic deforming force. The device 60 comprises a chamber 61 with an inlet opening 62

130 and a small nutlet opening 63 designed for

placement in or adjacent to a small incision 15. In this respect, the deforming force, either mechanical, hydraulic or pneumatic force, is applied through the inlet opening 62 of the device 60 in such a manner that the lens 30 is forced into and through the small outlet 63 and into the eye through the cannula 64 at the distal end of the device.

The intraocular lens 30 is initially positioned 10 in the chamber 61 between the source of pressure, for instance, a manual syringe 65 as depicted, or other suitable system, and the orifice 66 through which it will pass before entering the eye. Optionally, the lens holding 15 chamber 61 may be fabricated from a sterile transparent material so that the lens 30 may be inspected without opening the chamber 61 to avoid exposure of the contents to undesirable contamination. The device as shown in

20 Fig. 41, may comprise a relatively short nozzle 67 to facilitate anterior or posterior chamber lens placement. Alternatively, the device may be fitted with a relatively long nozzle 68 to facilitate placement of the lens 30 through 25 the pupil 12 into the posterior chamber 18.

Fig. 38 most clearly illustrates the lens holding chamber 61 of the device 60 shown in Fig. 37. The lens holding chamber 61 is preferably composed of transparent material 30 and appropriately designed to contain the lens 30 in a natural, unstressed state. Preferably, the lens 30 before insertion and within the chamber 61, is suspended in a suitable liquid medium such as distilled water, saline or a 35 biocompatible lubricating fluid such as hyaluronic acid or condroitin sulfate. As shown in Fig. 38, the chamber 61 in one embodied

form is adapted to hold a lens 30 without supporting appendages and having a circular 40 optical zone portion 31. However, it should be understood that such chamber can be adapted in a variety of configurations to facilitate placement of various intraocular lens structures in accordance with the present in-45 vention.

Fig. 39 depicts the lens 30 undergoing deformation by the action of fluid pressure as it is applied from the rear of the chamber 61 forcing the lens 30 into the narrow cannula 50 64 and outlet opening 63 which has been preplaced through the incision 15 made in the ocular tissue.

As shown in Fig. 40, the lens 30 returns to its natural, unstressed state as it exits from the relatively long nozzle 68 in the eye. In accordance with the present invention, the memory characteristics of the inventive lens are imparted by appropriate selection of lens material, and the combination of lens dimensions and fabricaton techniques which imparts the desired lens configuration. The deformable optical zone portion of the lens must have an elongation to break of at least about 50 percent and preferably in the range of from

higher

Fig. 41 further illustrates positioning of the lens holding chamber 61 of the device 60 shown in Fig. 37 equipped with a short nozzle 70 67 for releasing the lens 30 just through the incision 15, as an anterior chamber or posterior chamber (through iridectomy or pars plana) placement.

Fig. 42 illustrates an alternative embodi-75 ment in which an extension cannula creating a long nozzle 68 is utilized to facilitate placement of the lens 30 in the posterior chamber 18 through the pupil 12.

Figs 43 through 46 are cross-sectional 80 views of the lens 30 while deformed in the cannula 64 of the device 60. In this regard, Fig. 43 illustrates the lens 30 deformed in a rolled condition; Fig. 44 illustrates the lens 30 deformed in a folded condition, accordion

85 style fold; Fig. 45 illustrates a deformed lens 30 in a partly rolled and partly folded condition; and Fig. 46 illustrates a deformed lens 30 in a random "crumple" folded condition as might be anticipated in the implantation 90 techniques shown in Figs. 31 and 33.

Fig. 47 depicts yet another embodied implantation device 70 in accordance with the present invention of the "injection type". In this embodied form, the intraocular lens 30 is

95 packaged in a lens holding compartment 71 as generally shown in Fig. 38, but the compartment 71 is adapted for mounting beyond the orifice 66 of the device 70. Accordingly, in this procedure, the deformable lens 30 is

100 first removed from the compartment 71 and loaded into the cannula 72 of the device 70 shown in Fig. 47. The compartment 71 is thereafter detached, and the cannula 72 is inserted into the incision for placement of the

105 lens 30 in the eye. The lens holding compartment 71, is therefore provided with a small outlet 73 designed for snug engagement with the nozzle 74 of the device 70 for placement in or adjacent to a small incision in the ocular

110 tissue. The deformable lens is held in a substantially unstressed state until force, for instance, mechanical or suction, is applied through the outlet 73 in such a manner as to engage the lens 30 and draw it through the

115 outlet 73 and into the engaged nozzle 74 from which it will be injected into the eye.

In more detail, Fig. 48 illustrates one method of removing the lens 30 from the lens holding compartment 71 utilizing suction from

120 the cannula 72 and with or without corresponding positive pressure from the other side.

Fig. 49 shows an alternate method of loading the cannula 72 by utilizing a microhook or 125 connecting material 53 to pull the lens into place in a manner similar to that shown in

The device shown in Fig. 47 may comprise a valve, hole, or other inlet to facilitate the

to the nozzle 74.

Fig. 50 depicts yet another implantation instrument 75 designed to simultaneously grasp and compress the deformable intraocular lens 30 to allow insertion of the lens 30 directly or indirectly into the eye. The embodied device 75 is of the forceps type and comprises a forward end 76 to encase the lens therein when closed. The forceps type 10 device 75, may be modified as shown in Fig. 51 in which the ends 76', of the device are shortened and hollowed to compress the lens with a minimal amount of instrument material in the maximum cross-sectional volume pre-15 sent in the incision. Of course, other modifications to the device can be made such as the provision of holes, cut-outs and the like, to facilitate lens handling.

As shown in Fig. 52, the device 75 will 20 partly deform the intraocular lens when the forceps are in a partially closed state. Two plates or sheets 77 and 78 over and under the lens may be included to facilitate encasing the lens 30 entirely within the ends 76.

5 Fig. 53 thus illustrates the forceps type device 75 with a lens completely encased therein.

Fig. 54 illustrates an alternate arrangement of the forceps ends 76" so that the ends 76" 30 contact or hinge first at the top and then close at the bottom. A bowl-shaped compressing mechanism may optionally facilitate lens encasement for this embodied form which enhances lens release performance within the 35 eve.

Fig. 55 illustrates in more detail the embodied device 75" of Fig. 54. In Fig. 55, the lens 30 is completely encased within the ends 76" of the device.

O Fig. 56 further illustrates the surgical procedure for implantation of the lens 30 in the posterior chamber 18 through a relatively small incision 15 and iridectomy utilizing one embodied form of the forceps type device.

45 Fig. 57 depicts the use of a forceps type device 75 of the cut-away variety to place the lens 30 in the posterior chamber 18 through the pupil 12. It should be understood however, that these devices can readily position 50 the lens 30 in the anterior chamber 17 as well.

Figs. 58 and 59 depict yet another embodiment of the forceps type device. In this embodied form, the device 79 includes the use of hydraulic pressure to be applied for ejection of the lens 30 from the ends 76 and into the eye. In this respect, mechanical, hydraulic or pneumatic pressure may be exerted by a tube or pipe 80 mounted on an adjacent portion of 60 the device 79.

As previously mentioned, the present invention is readily adapted to implant lens for refractive correction of the human crystalline lens without removal thereof. As shown in 65 Figs. 60 and 61, the intraocular lens 47 is

placed in the posterior chamber 18 between the iris 11 and the human crystalline lens as shown in Fig. 60. The lens 47 illustrated is of the type shown in Figs. 19 and 20 herein.

70 Fig. 61 shows an alternate positioning of the lens 47 shown in Figs. 19 and 20 positioned in the anterior chamber 17 of the eye with the natural crystalline lens still intact and in place.

75 Typically, the inventive intraocular lens structure will have a total length of from about 9 millimeters to about 14 millimeters, a width of from about 4 millimeters to about 14 millimeters and can be fabricated having a

80 wide range of index of refraction. The deformable optical zone portion will typically have a thickness of from about .1 millimeters to about 1.0 millimeters and a diameter in the range of from about 4 millimeters to about 6 85 millimeters.

Any conventional method for manufacture of the inventive lens can be utilized in accordance with the present invention to insure that the lens has an elongation to break within

90 the prescribed range as aforementioned herein. For instance, compression molding, transfer molding, injection molding, casting, machining, or combination of these techniques may be utilized to produce the inven-95 tive lens.

The deformable intraocular lens structures in accordance with the present invention also facilitate removal of the lens from the eye atraumatically should a complication arise 100 after implant, necessitating its removal from the eye.

Those skilled in the art will readily appreciate that other less preferred procedures could be utilized to effect deformation of the lens 105 during implantation. For instance, a lens fabri-

cated from hydrophilic material could be implanted in a dry state and hydrated once in position to return to its desired configuration and fixed focal length. Alternatively, the lens

110 could be implanted in a plurality of separate components which are built up in the eye and suitably attached to one another, for instance by a medical grade adhesive.

The lens holding chamber and lens holding 115 compartment of the implantation devices depicted in Figs. 37 through 49 can, of course, be fabricated having a wide variety of suitable configurations for containing the deformable intraocular lens therein. In this respect, the

120 chamber and compartment having pre-deformed lenses contained therein can be conveniently dispensed separately from the injection type devices.

Additionally, the intraocular lens structure
125 in accordance with the present invention may
comprise a base member having at least one
surface layer thereon. For instance, a base
member composed of an elastomer can be
encased within a surface layer of hydophilic
130 material to enhance tissue comparability.

Accordingly, the present invention offers a unique implantation system for correction of or replacement of human crystalline lens after, for instance, cataract removal by way of small incision technique. The system therefore provides an implantation technique with attendant surgical safety, convenience and a comfortable fit for the eye.

The described lens implant procedures and 10 devices, thus minimize the principle disadvantages attendant with conventional rigid intraocular lens implantation which requires a relatively large incision in the ocular tissue which, among other disadvantages, leads to a rela-

15 tively high complication rate and longer recovery times.

It will be apparent from the foregoing that, while particular forms of the invention have been illustrated and described, various modifi-20 cations can be made without departing from the spirit and scope of the invention. Accordingly, it is not intended that the invention be limited, except as by the appended claims.

25 CLAIMS

- 1. An improved intraocular lens suitable for use as an artificial lens implant in an eye, said lens comprising a deformable optical zone portion having prescribed memory char-30 acteristics which enable the lens to be deformed by compressing, rolling, folding, stretching, said optical zone portion to a diameter of 80% or less of the cross-sectional diameter of said optical zone portion in an 35 unstressed state, yet return to its original configuration, full size, and fixed focal length after implantation in the eve.
- 2. The intraocular lens as defined in Claim 1 and further comprising means for support-40 ing said lens within the eye.
 - The intraocular lens as defined in Claim 2 wherein said means for supporting said lens within the eye comprises at least one appen-
- 4. The intraocular lens as defined in Claim 3 wherein said at least one appendage is a uniplanar appendage.
- 5. The intraocular lens as defined in Claim 2 wherein said at least one appendage is an 50 angulated appendage.
 - 6. The intraocular lens as defined in Claims 3, 4 or 5 wherein said appendage comprises an internal support element.
- 7. The intraocular lens as defined in Claim 55 6 wherein said internal support element is compressible.
 - 8. The intraocular lens as defined in Claim 1 and further comprising means for facilitating suturing of said lens in the eve.
 - 9. The intraocular lens as defined n Claim 1 and further comprising means for facilitating manipulation of said lens in the eye.
- 10. The intraocular lens as defined in Claim 1 and further comprising means for RE facilitating fluid flow through said lone in the

- 11. The intraocular lens as defined in Claims 8, 9 or 10 wherein said last-mentioned means is at least one passageway disposed 70 through said lens.
 - 12. The intraocular lens as defined in Claims 8, 9 or 10 wherein said last mentioned means is at least one depression disposed in said lens.
- 13. The intraocular lens as defined in Claim 1 wherein said optical zone portion is colored or tinted.
- 14. The intraocular lens as defined in Claim 1 wherein said optical zone portion 80 includes occluded portions.
 - 15. The intraocular lens as defined in Claim 1 wherein said optical zone portion comprises an elastomeric base member encased within a hydrophilic surface layer.
- 85 16. The intraocular lens as defined in Claim 2 wherein said means for supporting said lens within the eye is composed of a first material which is different from a second material used for fabricating said optical zone
- 17. The intraocular lens as defined in Claim 2 wherein said means for supporting said lens within the eye comprises a substantially continuous peripheral flange integral 95 with said optical zone portion.
- 18. The intraocular lens as defined in Claim 2 wherein said means for supporting said lens within the eye comprises a substantially continuous peripheral flange non-integral 100 with said optical zone portion.
 - 19. The intraocular lens as defined in Claim 1 wherein said optical zone portion is composed of a compound selected from the group consisting of silicone elastomers, poly-
- 105 urethane elastomers, hydrogel polymers, collagen compounds, organic gel compounds and synthetic gel compounds.
- 20. The intraocular lens as defined in Claim 2 wherein said optical zone portion is 110 suspended from a peripheral support ring.
- The intraocular lens as defined in Claim 36 wherein said suspension is effected by a plurality of threads connecting said optical zone portion to said peripheral support 115 ring.
- The intraocular lens as defined in 22. Claim 1 wherein said optical zone portion has either a biconvex, plano convex, plano concave, biconcave or concave-convex configura-120 tion.
 - 23. A surgical device for implantation of a deformable intraocular lens in the eye through a relatively small incision made in the ocular tissue, said device comprising a relatively rigid
- 125 shaft terminating at a forward end with first means for engaging a distal portion of said deformable intraocular lens and second means for engaging a proximal portion of said deformable intraocular lens and means for moving
- 130 said first means and said second means anart

from each other to produce a resultant deforming force on said optical zone portion of said lens.

- 24. A surgical device for implantation of an artificial intraocular lens in the eye through a relatively small incision made in the ocular tissue, said device comprising means for containing said intraocular lens having a deformable optical zone portion in a forward end of 10 said device; means for exerting a force on said lens sufficient to deform said lens and expel said lens from said device for placement of said lens in the eye.
- 25. A surgical device for implantation of
 15 an artificial intraocular lens in the eye through a relatively small incision made in the ocular tissue, said device comprising means for simultaneously grasping and compressing a deformable optical zone portion of said lens,
 20 said means being disposed at the forward end
 - of said device.

 26. An intraocular lens substantially as hereinbefore described with reference to, and as illustrated in. Figs. 3, 21, 21a, 22 and
- 25 22a, or these Figures as modified by Figs. 4 to 8; or Figs. 9 and 10; or Figs. 11, 12, 23 and 24; or Figs. 13, 14, 27 and 28; or Figs. 15, 16, 25 and 26; or Figs. 17 and 18; or Figs. 19, 20, 29 and 30; or Fig. 60; or Fig. 30 61 of the accompanying drawings.
- 27. A surgical device substantially as hereinbefore described with reference to, and as illustrated in, Figs. 31 and 32; or Fig. 33; or Fig. 34; or Figs. 35 and 36; or Figs. 37 to 35 46; or Figs. 47 to 49; or Figs. 50 to 52 and 56; or Fig. 53; or Figs. 54 and 55; or Fig. 57; or Figs. 58 and 59 of the accompanying drawings.
